General Procedures

Dry solvents were freshly distilled under argon from an appropriate drying agent before use. Bis(cyclooctadiene)iridium(I) tetrakis(3,5-bis(trifluoromethyl) phenyl) borate (abbreviated as \( \text{Ir(cod)}_2\text{BARF} \)), Bis(1,5-cyclooctadiene)iridium(I) tetrafluoroborate (abbreviated as \( \text{Ir(cod)}_2\text{BF}_4 \)), 1,2-Bis[bis(pentafluoro-phenyl)phosphino]ethane (abbreviated as dpp\(^{\text{F}}\)e) were purchased from Aldrich. Other bisphosphines were purchased from Aldrich or Strem-Chemicals. All other reagents used were bought from Aldrich, Alfa Aesar, TCI or Acros and used without further purification.

All reactions dealing with air- and moisture-sensitive compounds were carried out in oven-dried reaction flask under argon atmosphere with dry solvents. The abbreviation "rt" refers to reactions carried out approximately at 23 °C. Reaction mixtures were stirred using Teflon-coated magnetic stirring bars. Reaction temperatures were maintained using Thermowatch-controlled silicone oil baths. Thin-layer chromatography (TLC) was performed on silica gel plates and components were visualized by observation under UV light, and / or by treating the plates with p-anisaldehyde or phosphomolybdic acid solutions, followed by heating. Flash chromatography was carried out on silica gel unless otherwise stated. Dryings were performed with anhydrous \( \text{Na}_2\text{SO}_4 \) or \( \text{MgSO}_4 \).

Concentration refers to the removal of volatile solvents via distillation using a Büchi rotary evaporator followed by residual solvent removal under high vacuum. NMR spectra were recorded in CDCl\(_3\), at 300 MHz (Varian), 400 MHz (Varian) or 500 MHz (Varian). Carbon types and structure assignments were determined from DEPT-NMR. NMR spectra were analyzed using MestreNova© NMR data processing software (www.mestrelab.com). 1,3,5-Trimethoxybenzene was used as internal standard. The following abbreviations are used to indicate signal multiplicity: s, singlet; d, doublet; t, triplet; q, quartet; dd, double doublet; ddd, doublet of doublet of doublets; td, triple doublet; dt, doublet of triplets; dq, doublet of quartet; m, multiplet; br, broad. Mass spectra (ESI-MS) were acquired using IT-MS Bruker AmaZon SL at CIQUSS and also using chemical ionization (CI) electron impact (El), or electrospray ionization (ESI) at the CACTUS facility of the University of Santiago de Compostela. The reactions were monitored by TLC. Enantioselectivities were determined in an Agilent HPLC 1100 Series with Chiralpak IA, IB, IC, IA3 or OZ-H analytical columns.

[a] Conditions: 1 was added to a solution of complex [M] (x mol%) and L (y mol%) in dioxane and the mixture was heated at the indicated temperature. [b] Isolated yield. [c] The same result was obtained when the catalyst was generated from [Ir(cod)Cl]₂ (2.5 %), dFppe (5 %) and AgBF₄ (5 %). [d] The same result was obtained at 140 °C.

Hypothesis for the formation of products of type 3

The results obtained with the methyl and phenyl ketone derivatives 1c and 1w (Table S1, entries 14 and 15) would suggest that, for these substrates, an endo-cyclization to afford intermediates like II and III would be preferred, eventually leading to products of type 3 after a reductive elimination. The
reason for the formation of endo product 3 is not clear, but might be related to the weaker coordinating ability of the keto with respect to the amide group.

**Synthesis of the substrates for catalysis**

**General procedure A** for preparation of 1,6-diene precursors 1a, 1b, 1d, 1e, 1f, 1g, 1j, 1h and 1i (exemplified for the synthesis of 1f).

5-Hydroxy-N-methoxy-N-methylpentanamide (S1)

Prepared following a procedure described by Flick and coworkers.[1] 

AlMe₃ (60 mL, 120 mmol, 2.0 M in hexane) was added dropwise to a stirred solution of N,O-dimethylhydroxyl-amine hydrochloride¹ (11.7 g, 120 mmol) in dry CH₂Cl₂ (26 mL) at 0 °C. (CAUTION: The reaction is very exothermic). The mixture was stirred for 20 min at 0 °C and D-valerolactone (8.0 g, 80 mmol) of was added dropwise. After stirring at 0 °C for 20 min, the mixture was diluted with CHCl₃ (125 mL) and then HCl (aq) (15 mL, 0.1 N) was added dropwise at 0 °C. The mixture was stirred for 1 h, the organic phases were separated, dried, filtered, and concentrated under reduced pressure to give 5-hydroxy-N-methoxy-N-methylpentanamide (12.9 g, 99% yield) as a white solid. The NMR data was consistent with previous characterization.
5-((tert-Butyldimethylsilyl)oxy)-N-methoxy-N-methylpentanamide (S2)

Prepared following a modified procedure described by Stork and coworkers.[2]
imidazole (13.2 g, 194 mmol), tert-butyldimethylsilyl chloride (17.3 g, 115 mmol) and 4-dimethylaminopyridine (117 mg, 0.96 mmol) were sequentially added to a solution of 5-hydroxy-N-methoxy-N-methylpentanamide (12.9 g, 80 mmol) in CH₂Cl₂ (275 mL, 0.29 M). The solution was stirred for 15 minutes, water (10 ml) was added and the reaction mixture was extracted with Et₂O (3 x 10 mL). The combined organic extracts were washed with water and brine, dried and evaporated. The crude was purified by column chromatography on silica gel (1:1 Et₂O – hexane) to obtain the desired product as colorless oil (21.0 g, 95% yield). The characterization analysis was consistent with the previous data.²

7-((tert-Butyldimethylsilyl)oxy)-2-methylheptan-3-one (S3)[3]

iPrMgBr (98 mL, 98 mmol, 1.0 M) was added dropwise to a solution of 5-((tert-butyldimethylsilyl)oxy)-N-methoxy-N-methylpentanamide (S2, 9.0 g, 32.6 mmol) in Et₂O (220 mL, 0.15 M) at -78 ºC. The reaction was allowed to warm to rt and stirred overnight. Then Rochelle’s Salt (sat) (50 mL) was added at 0 ºC, the organic phase was separated and subsequently washed with NH₄Cl (sat) (250 mL), water (200 mL) and brine (200 mL). After extraction with Et₂O (3 x 280 mL), the combined organic extracts were dried and evaporated to yield a crude residue that was purified by column chromatography on silica gel (1:8 Et₂O – hexanes) to obtain the desired product (S3) as colorless oil (8.4 g, 57% yield) The NMR data is consistent with that previously described in literature.³

1-(2-Bromophenyl)-4-methylpentan-2-one (S7)

(2-Bromobenzyl)magnesium bromide was prepared following a modified procedure described by Whitesides et. al.[5] Under an inert atmosphere, magnesium turnings (1.1 equiv) were covered with Et$_2$O (0.35 M) and activated with iodine and 1,2-dibromoethane. A solution of bromobenzyl-bromide (1 equiv) in Et$_2$O (0.35 M) was added dropwise to the activated magnesium. The solution was refluxed for 20 min before being allowed to cool down to rt. The resulting solution containing the Grignard reagent (17.2 mmol) was
added dropwise to a solution of $N$-methoxy-$N,3$-dimethylbutanamide\(^4\) (6.88 mmol) at -78 °C in Et\(_2\)O (46 mL). The reaction was allowed to warm to rt and was stirred overnight. The mixture was cooled in an ice-water bath and a solution of Rochelle salt was added. NH\(_2\)Cl (sat) was added and the layers were separated. The aqueous phase was extracted with Et\(_2\)O and the combined organic phases were dried and concentrated to yield a crude residue that was purified by flash chromatography (from 1 : 40 to 1 : 10, Et\(_2\)O: Hexanes) to afford the desired product (S\(_7\)) as colorless oil (1.35 g, 77 % yield). \(^1\)H NMR (300 MHz, CDCl\(_3\)): δ 7.56 (dd, $J = 8.0, 1.3$ Hz, 1H), 7.27 (td, $J = 7.4, 1.3$ Hz, 1H), 7.20 (dd, $J = 7.6, 2.0$ Hz, 1H), 7.13 (ddd, $J = 7.9, 7.1, 1.9$ Hz, 1H), 3.83 (s, 2H), 2.38 (d, $J = 6.9$ Hz, 2H), 2.25 – 2.12 (m, 1H), 0.93 (d, $J = 6.6, 0.6$ Hz, 6H). \(^1\)C NMR (75 MHz, CDCl\(_3\)): δ 206.61 (C), 134.87 (C), 132.90 (CH), 131.82 (CH), 128.80 (CH), 127.65 (CH), 125.11 (C), 51.53 (CH\(_2\)), 50.55 (CH\(_2\)), 24.55 (CH), 22.66 (CH\(_3\)). Methyltriphenylphosphonium bromide (3.35 g, 9.40 mmol) was dissolved in benzene (20 mL) under argon. Sodium tert-butoxide (0.83 g, 8.62 mmol) was added portion wise to this solution and the mixture was refluxed for 2 hours. The yellow solution was allowed to reach rt, the ketone (S\(_7\), 3.92 mmol) in benzene (0.2 M) was added dropwise and the reaction was stirred overnight. Water (40 mL) and Et\(_2\)O (40 mL) were sequentially added. The layers were separated and the aqueous phase was extracted with Et\(_2\)O (2 x 40 mL). The combined organic layers were dried and concentrated. (E)-7-Methyleneundec-2-enoic acid (1v).

LiOH (42 mg, 0.178 mmol, 2 equiv) in water (3.3 mL) was added to a solution of ethyl (E)-7-methyleneundec-2-enoate (1u, 200 mg, 0.89 mmol, 1 equiv) in MeOH (1.6 mL) and THF (4 mL), and the reaction mixture was stirred at 45 ºC for 20 hours. Procedure for the Iridium-catalyzed intramolecular hydrocarbonation reaction

Ir(cod)$_2$BArF (0.05 equiv), $d^5$ppe (0.05 equiv), the carboxamide precursor (typically 50 -200 mg, 1.0 equiv) and the appropriate solvent [dioxane or 1,2-DCE (0.124 M)] were sequentially added to a Schlenk tube under Argon. The reaction mixture was then stirred at the appropriate temperature [100 °C for dioxane or 140 °C for 1,2-DCE (in a sealed tube)]. After 19 h, the reaction mixture was concentrated and the crude residue was purified by flash chromatography on silica gel (typically 1:20 to 1:10 EtOAc : Hexanes) to afford the cyclic product.

Control experiments related to the formation of E / Z isomers of 2r and 2s

Control experiments carried out for the cyclizations of 1r and 1s suggest that these mixtures are the result of an isomerization of the initially formed e-isomer (E- 2r, E-2s), presumably mediated by the Ir(I) catalyst (Scheme S1, eq. a). The isomerization is also observed during the isolation process in the contact to silica-gel (Scheme S1, eq. b).

Procedure for the enantioselective Ir-catalyzed intramolecular hydrocarbonation process

An oven dried schlenk tube equipped with a Teflon septum and magnetic stir bar was charged with L1 or L3 (5 mol%), Bis(1,5-cyclooctadiene)iridium(I) tetrafluoroborate (5 mol%), the amide substrate (1.0 equiv) and the solvent (dioxane or 1,2-DCE, 0.250 M). The reaction mixture was then stirred at 80 °C. After TLC indicated full conversion of the starting material, the reaction mixture was concentrated in vacuo. Purification of the crude product by flash chromatography on silica gel (typically 1:20 to 1:10 EtOAc : hexanes) afforded the desired product.

Determination of the Kinetic Isotope effect

In two different Schlenk flasks equipped with their respective stir ring bars, Ir(cod)\(_2\)BArF (24.7 mg, 0.019 mmol), dpp\(_{\text{F}}\)e (14.7 mg, 0.019 mmol) and 1\(k\) (100 mg, 0.389 mmol, Schlenk 1) or 1\(k'\) (101 mg, 0.389 mmol, Schlenk 2), were successively added under Argon. Dioxane (1.6 mL, each one) was then added and the flasks were sealed with rubber septa and placed in a pre-heated (70 °C) oil bath. Aliquots (300 \(\mu\)L) were taken at the times indicated in the Table S3 (for 1\(k\)) and Table S4 (for 1\(k'\)). The aliquots were filtered through a florisil pad and the volatiles were removed so that the the crude residues were taken and analyzed by \(^1\)H NMR.

Assignment of structure of 2t' was based on the HMBC, HSQC, COSY and nOe experiments.

Figure S1. Significant nOe signals observed for 2t'

The following control experiments, carrying out the cyclization of 1t at lower temperatures indicate that the observed isomerization of the pendant double bond occurs in the reaction media, after the initial formation of the expected, non-isomerized, product 2t.

Mechanistic probe: NMR spectra of D-2t', resulting from the cycloaddition of D-1t (related to Scheme 3, eq. 2, main manuscript)

As can be seen in the following Figures, deuteration of D-2t' is only observed at the methyl group of the quaternary stereocenter (signal at 1.40 ppm). While in 2t' the signal for this methyl group integrates for 3H, that of D-2t' corresponds to 2H. Accordingly, $^1$H-NMR spectra of D-2t' shows that deuterium is only located at this particular methyl group (1.40 ppm).
